

ABSTRACT
ILLUMINATION SYSTEM FOR DISPLAYING IMAGES WITHOUT COLOR
BREAK-UP

The invention relates to a system for displaying images comprising:

- a light source (1) emitting an illumination beam;
- a spatial light modulator (2) controlled by video control signals corresponding to a succession of image frames;
- a matrix filter (3) formed of a mosaic of elementary filters of various colors, illuminated by said illumination beam and transmitting a spatially filtered color beam to the spatial light modulator (2), an image of said filter being produced on an entrance face of the spatial light modulator;
- means of displacement for displacing the image of the filter (3) on the entrance face of the spatial light modulator (2) and
- a device (5) for controlling these means of displacement, making it possible to control at least one sequence of displacements of the image of the filter during each image frame.
